1) In the analyses we decided against including a dummy identifying multiple observations as we account for this by clustering standard errors at the individual level.
2) For the analyses of H2 we reversed the variable plh0004 (political attitudes) so that higher values indicate more left-leaning policies. We did so for a more intuitive interpretation of the results.
3) For H3, we did not operationalize gender equality in the household at couples-level. Retrospectively, we would have favored an approach that operationalizes this variable at couples-level using the parid (partner person number) variable.
