We had access to the 5% data sample when formulating the PAP. This was helpful to see how many observations we can expect for each variable and to, e.g., avoid control variables that are sparsely populated that would reduce power of the regressions. It also helped to make sure that the matching of couples via the partner id worked and to determine how many people remain unmatched. It further made us aware of some edge cases of partners who are still married to a different person or couples who state to do zero housework. This allowed to sharpen our exclusion restrictions. It is hard to anticipate some of these issues without data access. We did not use data access to check whether any of the hypotheses “work”, as this would be bad science and there was no incentive to do so.
