
As members of the "NoData" cluster, we had to make two minor changes to our analysis upon receiving access to the 5% sample of the data:

(1) The variable religion was not included in final regressions in contrast with the PAP because there were too few cases with valid info on religion in conjunction with other requisite variables.

(2) Instead of using age 18-24 years as the youngest age group we effectively used a broader age interval of 18-29 years, because there was only one case in our 5% data with agregr=18-24 and info on outcome for H1 - so this lowest group drops out and we effectively have a reference category of 18-29 years.
