Comment to the Pre-Analysis Plan

Included control variables (applies to H1-H4): In the PAP, it was specified that "we control for the number of children (sumkids)". Clarification: we did not simply control for the variable sumkids but created a new variable only counting the kids that were already born at the time of observation.

Further, we specified that we control for "education (pgbilzeit or d11108)". We did that by adding pgbilzeit and pgbilzeit^2 to the regression in order to better capture non-linear effects.

Finally, we did not include age in the control variables as specified in the PAP which was an oversight on our part.

Hypothesis 1. Having daughters leads to stronger support for gender equality (as measured by attitudes)

See clarification about included control variables above.

Hypothesis 2. Having daughters leads to more left-leaning political preferences

See clarification about included control variables above.

Divergence from specified outcomes: In the PAP, it was specified that "we begin by examining the effects on party leanings, followed by political intensity, and finally use the combined measure "leaning intensity" as the outcome variable." Since we were only able to report one result, we did choose to only report the outcome of the combined "leaning intensity" outcome.

Hypothesis 3. Having daughters leads to more gender equality in the household (as measured by behaviors or outcomes).

See clarification about included control variables above.

Hypothesis 4. Having daughters leads to a larger increase in the support of gender equality for men than for women (with gender equality measured by attitudes).

See clarification about included control variables above.

For H4, it was specified that we control for "occupational position (pgstib e11105)", which was a mistake in the PAP that was not corrected from an earlier version. Not including occupational position also aligned the analysis with H1-H3.
