#ManyDaughters PAP

H1: Having daughters leads to stronger support for gender equality (as measured by attitudes).

• Variables: Which variables will you include? How will these variables be coded— will you use them the way they are or recode them, and if so, how?

-y-variable gender_att, measured using "plh0395i05" Schools and preschools should promote non-gender-typical activities that are not typical for children's gender, on 1-7 Likert scale.

-x-variable: d_daughter, dummy for having a daughter, coded as 1 if any of variables "kidsex01"-"kidsex19" equals 2 (female child)

-controls:

i) age: measured as survey year ("syear") minus birth year ("gebjahr")

ii) male dummy: coded as 1 if "sex" equals 1 (male)

iii) immigrant dummy: coded as 1 if born overseas and did not enter Germany before 1950 ("germborn" equals 2)

iv) log net household income: measured as log("hghinc")

v) total number of years of education: measured using "pgbilzeit"

• Inclusion/exclusion criteria: Are there any observations you will exclude? If yes, which? Which years will you include/what period will you study?

I will only keep observations that fulfil the following:

i) from private households

ii) from the year 2019, when the y-variable was measured

iii) with non-missing data (on any of x, y, control variables)

• Exact analysis: Please write down the exact specification of the regression model, including the names of the dependent and independent variables, and whether you use robust standard errors or something else.

$$gender_att = a + b * d_daughter + X'c + e$$

where:

-gender_att is "plh0395i05" Schools and preschools should promote non-gender-typical activities that are not typical for children's gender, on 1-7 Likert scale.

-d_daughter is a dummy for having a daughter, coded as 1 if any of variables "kidsex01"-"kidsex19" equals 2 (female child)

-X' is a vector of control variables including age, male dummy, immigrant dummy, log net household income and total number of years of education

-e is the error term

I will use robust standard errors.

• Interpretation of results: Please specify which statistic you will take into account for testing the hypothesis. How do you interpret whether your test result is in line with the hypothesis or not?

If b, the coefficient of d_daughter, is positive and significant at the 5% level, I would consider the result in line with the hypothesis.

H2: Having daughters leads to more left-leaning political preferences.

• Variables: Which variables will you include? How will these variables be coded— will you use them the way they are or recode them, and if so, how?

-y-variable lr_scale, measured using "plh0004" left-right attitudes on a 0 (left) - 10 (right) scale.

-x-variable: d_daughter, dummy for having a daughter, coded as 1 if any of variables "kidsex01"-"kidsex19" equals 2 (female child)

-controls:

i) age: measured as survey year ("syear") minus birth year ("gebjahr")

ii) male dummy: coded as 1 if "sex" equals 1 (male)

iii) immigrant dummy: coded as 1 if born overseas and did not enter Germany before 1950 ("germborn" equals 2)

iv) log net household income: measured as log("hghinc")

v) total number of years of education: measured using "pgbilzeit"

• Inclusion/exclusion criteria: Are there any observations you will exclude? If yes, which? Which years will you include/what period will you study?

I will only keep observations that fulfil the following:

i) from private households

ii) with non-missing data (on any of x, y, control variables)

• Exact analysis: Please write down the exact specification of the regression model, including the names of the dependent and independent variables, and whether you use robust standard errors or something else.

$$lr_scale = a + b * d_daughter + X'c + d_s + e$$

where:

-lr_scale is "plh0004" left-right attitudes on a 0 (left) - 10 (right) scale.

-d_daughter is a dummy for having a daughter, coded as 1 if any of variables "kidsex01"-"kidsex19" equals 2 (female child)

-X' is a vector of control variables including age, male dummy, immigrant dummy, log net household income and total number of years of education

-d_s is survey year fixed effects

-e is the error term

I will cluster errors at the individual level.

• Interpretation of results: Please specify which statistic you will take into account for testing the hypothesis. How do you interpret whether your test result is in line with the hypothesis or not?

If b, the coefficient of d_daughter, is negative and significant at the 5% level, I would consider the result in line with the hypothesis.

H3: Having daughters leads to more gender equality in the household (as measured by behaviors or outcomes).

• Variables: Which variables will you include? How will these variables be coded— will you use them the way they are or recode them, and if so, how?

-y-variable household gender disparity, measured as total weekly childcare hours by female partner minus male partner. Weekly childcare hours are measured as the sum of childcare hours during weekdays (pli0044_v3), Saturday (pli0019_v4) and Sunday (pli0022_v4)

-x-variable: h_daughter, dummy for having a daughter, coded as 1 if any of variables "kidsex01"-"kidsex19" equals 2 (female child) for either partner

-controls:

i) average age of partners: age measured as survey year ("syear") minus birth year ("gebjahr")

ii) immigrant dummies: dummies for having 1 or 2 persons with immigrant background, defined as born overseas and did not enter Germany before 1950 ("germborn" equals 2)

iii) log net household income: measured as log("hghinc")

iv) average total number of years of education: total number of years measured using "pgbilzeit"

• Inclusion/exclusion criteria: Are there any observations you will exclude? If yes, which? Which years will you include/what period will you study?

I will only keep observations that fulfil the following:

i) from private households

ii) with non-missing data (on any of x, y, control variables)

iii) households with non-missing partner

iv) households with 1 pair of partners

v) households with heterosexual couple

• Exact analysis: Please write down the exact specification of the regression model, including the names of the dependent and independent variables, and whether you use robust standard errors or something else.

$$disparity = a + b * h_daughter + X'c + d_s + e$$

where:

-disparity is total weekly childcare hours by female partner minus male partner. Weekly childcare hours are measured as the sum of childcare hours during weekdays (pli0044_v3), Saturday (pli0019_v4) and Sunday (pli0022_v4)

-h_daughter is a dummy for having a daughter, coded as 1 if any of variables "kidsex01"-"kidsex19" equals 2 (female child) for either partner

-X' is a vector of control variables including household average age, dummies for 1 or 2 immigrant-background partners, log net household income and average total number of years of education

-d_s is survey year fixed effects

-e is the error term

I will use robust standard errors.

• Interpretation of results: Please specify which statistic you will take into account for testing the hypothesis. How do you interpret whether your test result is in line with the hypothesis or not?

If b, the coefficient of d_daughter, is negative and significant at the 5% level, I would consider the result in line with the hypothesis.

H4: Having daughters leads to a larger increase in the support of gender equality for men than for women (with gender equality measured by attitudes).

• Variables: Which variables will you include? How will these variables be coded— will you use them the way they are or recode them, and if so, how?

-y-variable gender_att, measured using "plh0395i05" Schools and preschools should promote non-gender-typical activities that are not typical for children's gender, on 1-7 Likert scale.

-x-variable: d_daughter, dummy for having a daughter, coded as 1 if any of variables "kidsex01"-"kidsex19" equals 2 (female child)

-controls:

i) age: measured as survey year ("syear") minus birth year ("gebjahr")

ii) male dummy: coded as 1 if "sex" equals 1 (male)

iii) immigrant dummy: coded as 1 if born overseas and did not enter Germany before 1950 ("germborn" equals 2)

iv) log net household income: measured as log("hghinc")

v) total number of years of education: measured using "pgbilzeit"

• Inclusion/exclusion criteria: Are there any observations you will exclude? If yes, which? Which years will you include/what period will you study?

I will only keep observations that fulfil the following:

i) from private households

ii) from the year 2019, when the y-variable was measured

iii) with non-missing data (on any of x, y, control variables)

• Exact analysis: Please write down the exact specification of the regression model, including the names of the dependent and independent variables, and whether you use robust standard errors or something else.

$$gender_att = a + b1 * d_daughter + b2 * male + b3 * male * d_daughter + X'c + e$$

where:

-gender_att is "plh0395i05" Schools and preschools should promote non-gender-typical activities that are not typical for children's gender, on 1-7 Likert scale.

-d_daughter is a dummy for having a daughter, coded as 1 if any of variables "kidsex01"-"kidsex19" equals 2 (female child)

-male is dummy for "sex" equals 1 (male)

-X' is a vector of control variables including age, male dummy, immigrant dummy, log net household income and total number of years of education

-e is the error term

I will use robust standard errors.

• Interpretation of results: Please specify which statistic you will take into account for testing the hypothesis. How do you interpret whether your test result is in line with the hypothesis or not?

If b3, the interaction coefficient of male*d_daughter, is positive and significant at the 5% level, I would consider the result in line with the hypothesis.
